

EE21B055 DSP Mini Project Report  
EE21B057  
Image categorization using CNN's

Introduction :

In this project, we will apply deep convolutional neural networks to classify images.

We are using a famous dataset known as "Cifar-ten". The dataset consists of several images divided into 10 categories such as planes, dogs, frogs, horses and trucks etc.

Understandings from this project :

\* The theory and intuition behind deep Convolutional neural networks.

\* Basics of digital image processing, performing 2D convolutions, max pooling and average pooling.

\* Building a CNN model to perform image classification using keras.

\* Optimize network weights using optimizer (Adam).

\* Evaluating the model and presenting the results using confusion matrices.

\* Save and retrieving trained network weights.

## PROJECT OVERVIEW:

\* CIFAR-10 is dataset that consists of several images divided into the following 10 classes:

- Airplanes, Cars, Birds, Cats, Deer, Dogs, Frogs, Horses, Ships, Trucks.

\* CIFAR-10 is widely used for machine learning and computer vision applications.

\* The dataset consists of 60,000 images, each image is  $32 \times 32$  pixels, (6000 images of each class).

In this we take all the data provided and then we divide it into : 80% for training and 20% for testing.

We adjust the weights here within our classifier model; and then once the network is trained we bring the testing data. Finally, will give the output of classified images.

## CNN Overview:

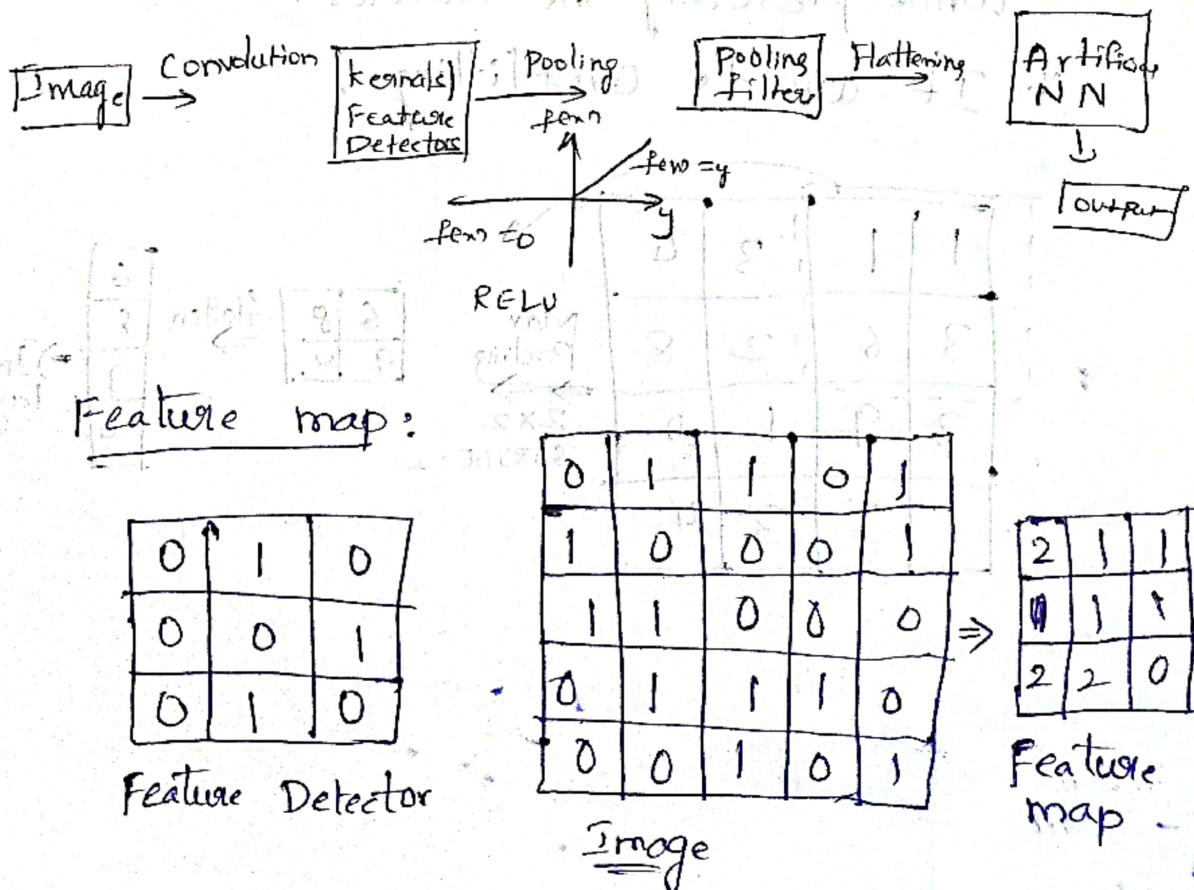

Step 1: Convolution (feature extraction / feature detection)

Step 2: adding (RELU Layer) Activation function

Step 3: Applying Pooling Layer (Down sampling)  
(like compressing an image) (which will improve the computational performance of the network and reduces the computational complexity)

Step 4: Flattening (pixels, we make them in one array)

Step 5: Feeding it in Artificial Neural network

## x. RELU Layer:

This is used to add non linearity in the feature map.

$$\text{It gives: } f(y) = \begin{cases} 0 & \text{for } y < 0 \\ y & \text{for } y \geq 0 \end{cases}$$

It enhances the sparsity or how scattered the feature map is.

## Pooling (Down sampling):

x. Pooling or down sampling layers are placed after convolutional layers to reduce feature map dimensionality.

x. This improves computational efficiency while preserving the features.

x. It avoids over-fitting.

## Improving Network Performance:

2. Improve accuracy by adding feature detectors / filters or adding a dropout.

Dropout  $\uparrow \Rightarrow$  Co-dependency  $\downarrow \Rightarrow$  Overfitting  $\downarrow$ .

## Code Involves:

Step 1: Importing Libraries / Datasets.

Includes: pandas, numpy, matplotlib, seaborn.

Techstacks Used:

# STEP #1: IMPORT LIBRARIES/DATASETS

```
] import pandas as pd  
import numpy as np  
import matplotlib.pyplot as plt  
import seaborn
```

Step 2: Visualising Data.

## STEP #2: VISUALIZE DATA

```
i = 10001  
plt.imshow(X_train[i])  
print(y_train[i])
```

[6]

Step 3: Data preparation:

This step involves, converting the data from decimal to binary numbers.

Step 4: Training the model:

Tech Stack Used:

1. Sequential - Building our model in a sequence fashion.

2. Conv 2D: Convolution Process

3. Max pooling: Will do down sampling

4. Average pooling: We just average the values of the pixels.

5. Dense: Creates fully connected Artificial Neural network.

6. Flatten: For flattening the map into a single array.

7. Dropout: Performs regularization, means dropping a couple of neurons, just to improve the generalization capability of the network.

## STEP #4: TRAIN THE MODEL

```
from keras.models import Sequential
from keras.layers import Conv2D, MaxPooling2D, AveragePooling2D, Dense, Flatten, Dropout
from keras.optimizers import Adam
from keras.callbacks import TensorBoard
from keras.optimizers import RMSprop
```

```
from keras.models import Sequential
from keras.layers import Conv2D, MaxPooling2D, Dropout, Flatten, Dense
from keras.optimizers import RMSprop

cnn_model = Sequential()
cnn_model.add(Conv2D(filters=64, kernel_size=(3, 3), activation='relu', input_shape=Input_shape))
cnn_model.add(Conv2D(filters=64, kernel_size=(3, 3), activation='relu'))
cnn_model.add(MaxPooling2D(2, 2))
cnn_model.add(Dropout(0.4))
```

Steps:

Evaluating the model:

Obtained, outputs (predicted) are almost 90% accurate.

Note: Each <sup>and every</sup> time, it will take different set of images, so the accuracy might vary.
